TELEVISION PROGRAMMES

Markova danced *Blue Bird* with Harold Turner before King George V and Queen Mary. She will be seen in the same ballet today with Anton Dolin.

Markova, a student of Seraphina Astafieva, joined the Diaghilev Ballet in 1924, appearing in *Swan Lake*, *Aurora's Wedding*, *Cimarosiana*, *The Cat*, and *The Story of the Nightingale*. This, and her subsequent work with the Ballet Club, the Camargo Society, and the Vic-Wells company, put her in the first rank of prima ballerinas. Sadler's Wells enthusiasts will remember her dancing in a special season of ballet with Dolin in 1935.

Dolin, whose real name is Patrick Healey-Kay, is a dancer whose fame is known all over the world. He made his first appearance on the stage at the Prince's Theatre in 1916.

9.35 'PICTURE PAGE'
(Fifty-Fourth Edition)

A Magazine Programme of General and Topical Interest

Edited by CECIL MADDEN

Produced by ROYSTON MORLEY

The Switchboard Girl : JOAN MILLER

A characteristic of Cecil Madden's 'Picture Page' that has made it a distinctive part of television programmes has been its unfailing topicality. The big events of the day, celebrities who are headlined in newspapers and eagerly discussed by the public, little-known people who have interesting tales to tell—all these have been featured. This evening's edition will be appropriate to the occasion, the eve of Coronation Day.

Because of programme alterations made necessary by the televising of the Coronation, both editions of 'Picture Page' this week are being televised today instead of tomorrow.

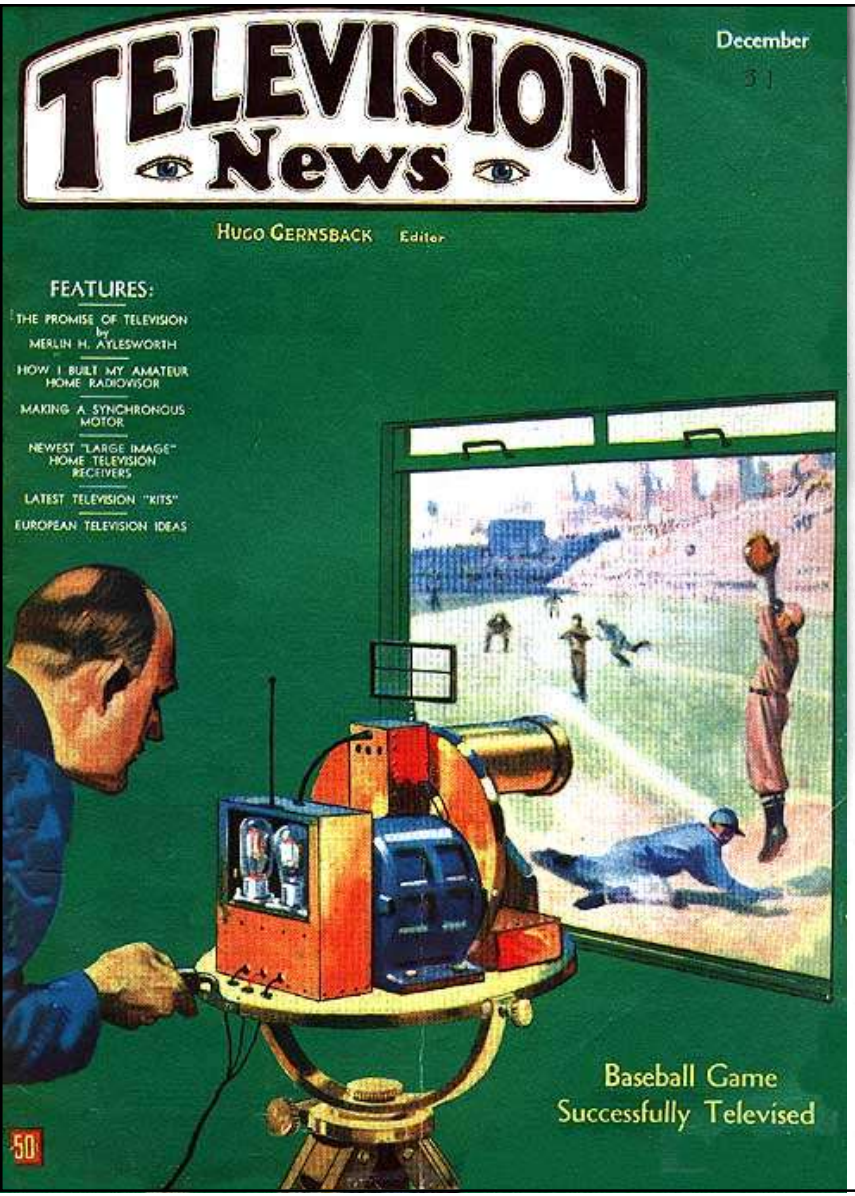
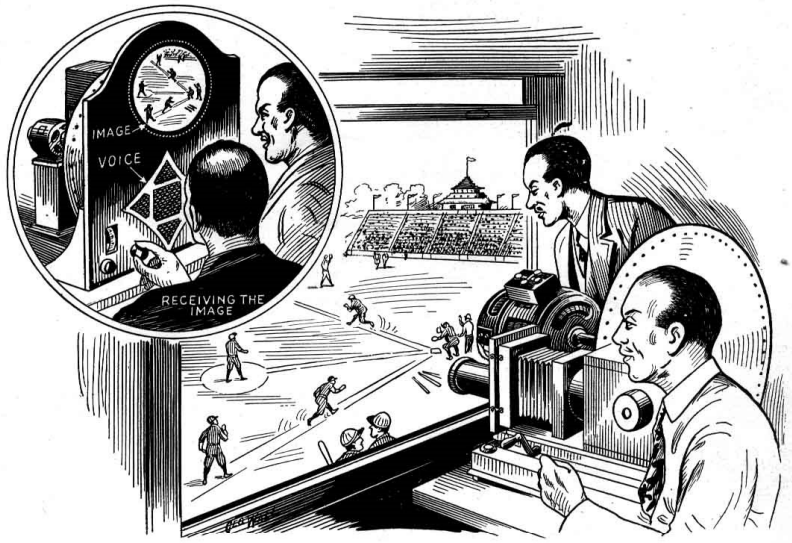
HIGH DEFINITION TELEVISION

27. With a view to extending the application of Television to a wider field and thereby increasing its utility and entertainment value, much attention has been given in recent years to the problem of obtaining better definition and reduced "flicker" in the received pictures.

28. The degree of definition it is essential to obtain is necessarily a matter of opinion, but the evidence received and our own observations lead us to the conclusion that it should be not less than 240 lines per picture, with a minimum picture frequency of 25 per second. The standard which has been used extensively for experimental work

it should be not less than 240 lines





Our artist's picture reproduced above from a photograph appearing in a Japanese magazine, shows that they are wide-awake indeed on television in Japan, for we have not reached the stage in America where we are televising ball-games, although the technical equipment available here is capable of doing so. We predict that by next summer we shall see ball games televised over more than one television system in this country.

STRIKE ONE! GREETS JAPANESE VISUALISTS

By H. WINFIELD SECOR

JAPAN is wide-awake when it comes to the latest advances in television, as the accompanying picture clearly demonstrates. This illustration was made by our staff artist from a photograph, showing a baseball game being televised in Japan. In the illustration shown on our front cover, the apparatus has been somewhat modernized by placing the televisor on gimbals, so that it can be quickly pointed, in any direction, by the operator. Judging by the original photograph, which appeared in a Japanese magazine, the televisor utilized for picking up the baseball game was a stationary affair, and it evidently was focused across the home plate. In the last issue of TELEVISION NEWS, we showed how the Baird experts, in conjunction with the British Broadcasting Company, recently televised the famous English "Derby", so that the present instance affords another link in the chain of evidence that television is indeed marching forward.

Recently a Japanese magazine contained a photograph showing a baseball game being televised. The recent television broadcast of the English Derby, coupled with the televising of fistic encounters in America, demonstrates that television is steadily marching forward.

Public Anxious to "See" Sporting Events

American *visualists*, by the tens-of-thousands, are waiting for the day when prizefights and other athletic events will come to their homes via the television screen. Probably this coming winter will see the first prize-fight shown via television—that is actual prize matches in such large places as Madison Square Garden, New York City. As a matter of actual fact, the Columbia Broadcasting System have shown several "prize ring" scenes over their television station, W2XAB (107 meters) accompanied by voice over W2XE (49 meters). Mr. William Schudt, director of television programs for the Columbia Broadcasting System, and his staff, especially arranged these "studio" boxing scenes between well-known exponents of the fistic art.

About three years ago, the writer saw what was probably the first demonstration, in America, of an "outdoor" pick-up as given by the Bell Telephone Laboratories. At that time a man going through various motions with a tennis racket, was shown on the television screen, which utilized a 60-line scanner. Public demonstrations by the Bell Telephone Laboratories, since then, have been practically all confined to "close-ups" such

WRNY to Start Daily Television Broadcasts; Radio Audience Will See Studio Artists

The first regul..r broadcasting of images by television over the radio from New York will begin tomorrow, it was learned last night from Station WRNY in the Hotel Roosevelt. WRNY, which is owned by The Radio News Magazine, has recently transmission as an intermittent high-pitched whirr, varying with the action before the transmitter.

Officers of WRNY saw the images at a set installed in a private home a few hundred yards from the transmitting station.

THE TELECTROSCOPE.

By LEON LE PONTOIS.*

I DESIGNATE by this name an apparatus having for its object the transmission of pictures or views of moving or stationary objects at great distances, and as I use electricity for the purpose of obtaining this result, I call this apparatus a telectroscope.

First let me say that by the transmission of pictures to great distances I do not mean the graphic transmission of sketches or writing as done, for instance, by the very ingenious invention of Prof. Elisha Gray, namely, the telautograph.

I intend to describe to you to-night the general outline of an apparatus that I have conceived for the purpose of seeing over as great distances as we hear by the long distance telephone.

D 1891 "Phon. - Tel."

THE CHICAGO EVENING POST

TUESDAY, MAY 12, 1891.

EDISON'S IN CHICAGO.

The Wizard of Menlo Park Stopping at the Auditorium.

TELLS OF HIS LATEST INVENTION

Thomas A. Edison is in the city. The wonder of the age, one of the world's truly great, he bears his honors easily. Naught is there about him to suggest the egotist. A massive head is his, but it is not "big." He is one of those rare men who achieve success and wear it as an ornament. In short, he is approachable as when he started on his great career. In him indeed the lightning has a kind master.

As he entered the Auditorium Hotel this morning the throng that filled the rotunda parted to let him pass. But few knew of his coming, but nearly all recognized his strong, clean cut features from familiarity

THOMAS A. EDISON.

"The electrical exhibit should be together," he said quietly, but with the earnestness of absolute conviction. "The exhibit at the Paris exhibition was divided into many parts, so that to see them all required one to walk about fifty miles. It was a fine display, but its effect and much of its value was lost by reason of its not being together.

"It will be a great mistake to separate the exhibit here. As Professor Barrett, a very worthy, able man, says, it should be together. It might not be of harm to have the dynamos in one building and the rest of the exhibit in another; still, the greatest effect is to be obtained from a grouping of the whole."

Mr. Edison has a cogent explanation of the desire to separate the exhibit.

"It is due to the existence of a commercial nigger in the woodpile," he said with [illegible] "wherein everybody nodded and wondered why he himself had not thought of it before. But the wizard hopes that the commercial nigger will be discovered and ousted and thus by centering the electrical exhibits in one spot obtain a display that has never yet been equaled in the world.

It has been stated that the invention which Mr. Edison is to exhibit at the fair as his piece de resistance is something that will surpass in its surprises anything that ever came from his wonderful workshop. The first wonder was the telephone and following it the phonograph. The one destined for Chicago to present to the world will embrace the elements of both and be equal if it do not exceed the sum of their combined mysteries.

"But," he explained, "this invention will not have any particular commercial value. It will be rather of a sentimental worth. What is it? We-el"—he hesitated as if loth to part with his secret, then seeing the look of expectancy in the faces of his listeners released a diminutive laugh and said:

"It is not yet completed. But when it is it will surprise you. I hope to be able by the invention to throw upon a canvas a perfect picture of anybody and reproduce his words. Thus, should Patti be singing somewhere, this invention will put her full length picture upon the canvas so perfectly as to enable her to distinguish every feature and expression of her face, see all her actions and listen to the entrancing melody of her peerless voice. The invention will do for the eye what the phonograph has done for the voice and reproduces the voice as well, in fact more clearly. I have already perfected the invention so far as to be able to picture a prize fight—the two men, the ring, the intensely interested faces of those surrounding it—and you can hear the sound of the blows, the cheers of encouragement and the yells of disappointment. And when

"The telephone is old," he said; "I want something fresh to attract my mind."

He was much pleased to learn of the progress being made by the officials of the world's fair.

"Everything is running smoothly," said an acquaintance, "and a little variety is now and then given to the work by Colonel Phoebe Couzins."

"Ah," said the wizard, raising his hand in supplication, "a woman is a wonderful being, full of mystery and hard to man[illegible] ago——"

"As electricity!"

"Harder."

It is not expected, as has been stated, that Mr. Edison will take any part in [illegible] Barrett's controversy [illegible] building. As [illegible] he is not [illegible] he expects to spend a great deal of money on his exhibit, but like all the other great electrical firms is willing to trust Professor Barrett with the preliminary arrangements. He has had world's fair talks with the electrical chief and pronounces him a man of good hard sense, able to work up the best electrical exhibit that has ever been brought together. Mr. Edison's own exhibit will be one of the wonders. The Eiffel tower was the only greater attraction at Paris than the Edison exhibit, and the great inventor is confident that his showing here will be equally prominent.

EDISON HIS OWN DOCTOR.

An Interesting Chat on Interesting Topics with the Wizard of Menlo Park.

Some time ago Mr Edison was ill, says the New York *Sunday Sun*, and there was consternation in his home and among his helpers in the workshops. Everybody in the shops, from the small boy who politely evades questioning visitors and successfully avoids betraying Mr. Edison's whereabouts, to the chief lieutenant of the great man, was greatly concerned. His immediate associates overwhelmed Mr. Edison with advice, and all besought him to call in a physician. Mrs. Edison was anxious, too, but very properly refrained from offering any opinions, feeling confidence in her husband's ability to choose the wisest course. He approved of her silence on this subject, and lectured his [illegible] friends thus:

"My friends, you are deceived. I am [illegible] not well, but my ailment is not serious if properly treated. If I were to follow your advice, take all the drugs that you suggest or all that the physician you advise me to call in would prescribe, I would be worse. The fact is my liver is out of order and my kidneys are not in just the condition they should be. I will remedy all that very speedily. My cure will be a change of diet. That is all that is needful in such a case. Come to think of it, I have been eating a great deal of meat lately; now I will stop eating meat altogether and will eat only vegetables."

But

1891: Edison said he might introduce color TV at the World's Columbian Exposition

of the singers. When the system is perfected, which I hope will be in time for the fair, the muscles of the singer's face, every glance of the eye, and each expression will be seen. Every colour in the performer's attire, too, will be exactly reproduced. Moreover, the spectator, seated by his own fireside, will see each person in the play move to his or her position in a natural way, just as though they were the very persons themselves."

AN ELECTRIC TELESCOPE.

[15374.]—It may be of interest to your readers to know the details of some experiments on which I have been engaged during the last three months, with the object of transmitting a luminous image by electricity.

To transmit light alone all that is required is a battery circuit with a piece of selenium introduced at the transmitting end, the resistance of which falling as it is exposed to light increases the strength of the current, and renders a piece of platinum incandescent at the receiving end thus reproducing the light at the distant station.

By using a number of circuits, each containing selenium and platinum arranged at each end, just as the rods and cones are in the retina, the selenium end being exposed in a camera, I have succeeded in transmitting built-up images of very simple luminous objects.

An attempt to reproduce images with a single circuit failed through the selenium requiring some time to recover its resistance. The principle adopted was that of the copying telegraph, namely, giving both the platinum and selenium a rapid synchronous movement of a complicated nature, so that every portion of the image of the lens should act on the circuit ten times in a second, in which case the image would be formed just as a rapidly-whirled stick forms a circle of fire. Though unsuccessful in the latter experiment, I do not despair of yet accomplishing my object as I am at present on the track of a more suitable substance than selenium.

THE

SCOTS MAGAZINE.

FEBRUARY, 1753.

—An expeditious method of conveying intelligence by means of electricity 73.

To the author of the SCOTS MAGAZINE.

SIR, Renfrew, Feb. 1. 1753.

IT is well known to all who are conversant in electrical experiments, that the electric power may be propagated along a small wire, from one place to another, without being sensibly abated by

air. To prevent the objection, and save longer argument, lay over the wires from one end to the other with a thin coat of jeweller's cement. This may be done for a trifle of addditional expence; and as it is an *electric per se*, will effectually secure any part of the fire from mixing with the atmosphere.——*I am, &c.*

EFFECT OF LIGHT ON SELENIUM DURING THE PASSAGE OF AN ELECTRIC CURRENT.

BEING desirous of obtaining a more suitable high resistance for use at the Shore Station in connection with my system of testing and signalling during the submersion of long submarine cables, I was induced to experiment with bars of selenium, a known metal of very high resistance. I obtained several bars varying in length from 5 to 10 centimetres, and of a diameter from 1 to 1½ millimetres. Each bar was hermetically sealed in a glass tube, and a platinum wire projected from each end for the purpose of connection.

The early experiments did not place the selenium in a very favourable light for the purpose required, for although the resistance was all that could be desired—some of the bars giving 1,400 megs. absolute—yet there was a great discrepancy in the tests, and seldom did different operators obtain the same result. While investigating the cause of such great differences in the resistance of the bars, it was found that the resistance altered materially according to the intensity of light to which it was subjected. When the bars were fixed in a box with a sliding cover, so as to exclude all light, their resistance was at its highest, and remained very constant, fulfilling all the conditions necessary to my requirements; but immediately the cover of the box was removed, the conductivity increased from 15 to 100 per cent. according to the intensity of the light falling on the bar. Merely intercepting the light by passing the hand before an ordinary gas-burner placed several feet from the bar increased the resistance from 15 to 20 per cent. If the light be intercepted by rock salt or by glass of various colours, the resistance varies according to the amount of light passing through the glass.

To ensure that temperature was in no way affecting the experiments, one of the bars was placed in a trough of water so that there was about an inch of water for the light to pass through, but the results were the same; and when a strong light from the ignition of a narrow band of magnesium was held about nine inches above the water the resistance immediately fell more than two-thirds, returning to its normal condition immediately the light was extinguished.

Effect of Light on the Electric Conductivity of Selenium

IT is of course impossible not to feel intense interest in the statement (NATURE, vol. vii. p. 303) which Mr. Willoughby Smith makes and which Mr. Latimer Clark endorses. That I have been unable to obtain the same result has doubtless been due to my having worked under conditions different from those existing in Mr. Smith's experiments. My failure has not been one of degree, but has been absolute. I have not only been unable to find that light increases the electric conductivity of selenium, but I have failed to get a current through selenium at all, even through a thickness of 0·1 millimetre. As I do not know how to put myself at once in direct communication with Mr. Smith, perhaps you will permit me to ask him through your columns to guide me on the following points :—

(*a.*) What was the form of battery employed, and what its power of overcoming British Association units of resistance?

(*b.*) What was the molecular condition of the "metal" (*sic*) employed,—*vitreous* or *crystalline*?

(*c.*) Where can "bars" of selenium be obtained which will afford the results stated?

(*d.*) Are there any unstated conditions essential to the successful production of the phenomenon?

1st STE president, 1872

Lecture at the Royal Institution

WEEKLY EVENING MEETING,

Friday, February 18, 1876.

GEORGE BUSK, Esq. F.R.S. Treasurer and Vice-President, in the Chair.

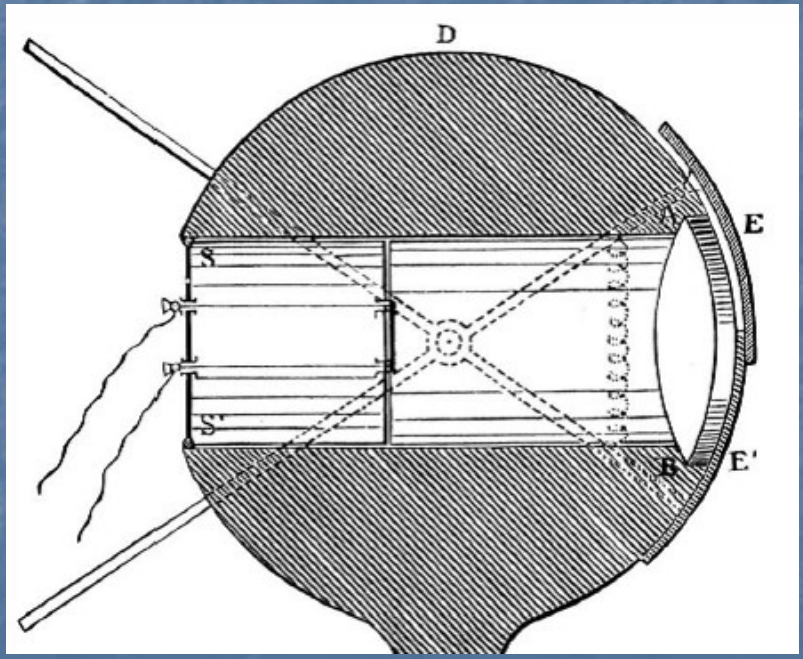
C. WILLIAM SIEMENS, Esq. D.C.L. F.R.S. M.R.I.

The Action of Light on Selenium.

WHEN, upon former occasions, I have ventured upon this arena, it has been for the purpose of placing before you the results of inquiries of my own into special subjects, which circumstance gave me some title to your indulgence.

This evening I cannot claim the same advantage, because the subject matter which I am about to bring before you is almost entirely the result of the investigations of others, and especially of my brother,

Before concluding, I wish to introduce to your notice a little apparatus which I have prepared to illustrate the extraordinary sensitiveness of my brother's selenium preparations, and an analogy between its action and that of the retina of our eye. It consists of a



Here we have then an artificial eye which is sensible to light

ARTIFICIAL EYES MADE SENSITIVE TO LIGHT.

Among the curious developments of Science is the recent production, by Dr C. W. Siemens, of an artificial eye that is sensitive to light. We wish we could add that it gives vision to the blind; but we cannot, though perhaps it contains a germ of promise in that direction. The new eye is composed of an ordinary glass lens, backed by an artificial retina of selenium. This mineral resembles and is allied to sulphur; it is distilled from bodies that contain sulphur in conjunction with metals, such as iron pyrites, a compound of sulphur and iron.

Notes.

Had my first idea of a (Selenium Electrical Camera) in 1876 after reading an article in December 9 - Page 374 (Scientific American) 1876. I have studied on the idea since then more or less and in January 1877 had worked up the instrument shown on pages 13 - 15 - 17 and so called this date the time of invention although I might with good reason only I invented it between 1876 & 1879 - The Instruments on pages 18 & 21 were invented in June 1878. But I had my first idea of them some months before this date.

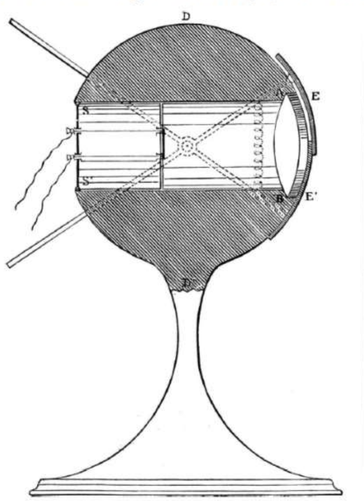
SIEMENS' SENSITIVE ARTIFICIAL EYE.

We have already alluded to Dr. William Siemens' curious device of an artificial eye sensitive to light, an invention

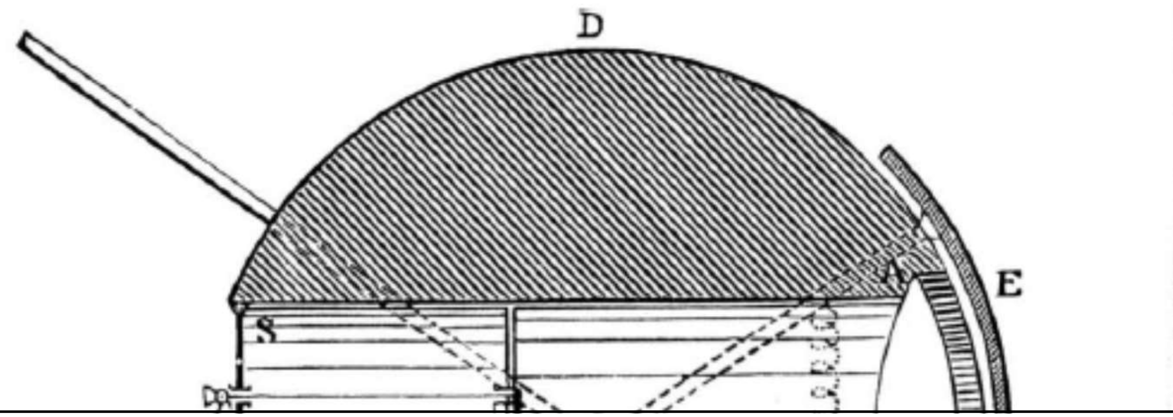


based upon the action of light upon the electric conductivity of selenium. The construction of the eye is shown in the annexed engraving.

A hollow sphere, suitably supported, is provided with two openings, in one of which is placed a converging lens, A B,

SIEMENS' SENSITIVE ARTIFICIAL EYE.

We have already alluded to Dr. William Siemens' curious device of an artificial eye sensitive to light, an invention



AN ELECTRIC TELESCOPE.

[15374.]—It may be of interest to your readers to know the details of some experiments on which I have been engaged during the last three months, with the object of transmitting a luminous image by electricity.

To transmit light alone all that is required is a battery circuit with a piece of selenium introduced at the transmitting end, the resistance of which falling as it is exposed to light increases the strength of the current, and renders a piece of platinum incandescent at the receiving end thus reproducing the light at the distant station.

By using a number of circuits, each containing selenium and platinum arranged at each end, just as the rods and cones are in the retina, the selenium end being exposed in a camera, I have succeeded in transmitting built-up images of very simple luminous objects.

An attempt to reproduce images with a single circuit failed through the selenium requiring some time to recover its resistance. The principle adopted was that of the copying telegraph, namely, giving both the platinum and selenium a rapid synchronous movement of a complicated nature, so that every portion of the image of the lens should act on the circuit ten times in a second, in which case the image would be formed just as a rapidly-whirled stick forms a circle of fire. Though unsuccessful in the latter experiment, I do not despair of yet accomplishing my object as I am at present on the track of a more suitable substance than selenium.

Television Inventions.

IN NATURE of April 27, p. 637, a notice appeared of a book by Mr. C. Francis Jenkins, of Dayton, Ohio, entitled "Radiomovies, Radiovision, Television". With some difficulty I have obtained a copy of this book from America, and find in it, in a picture which appears to be on page 74 (though no paging is given), a description copied from a journal of July 25, 1894, ascribing to C. Francis Jenkins an apparatus for transmitting pictures by electricity, under the name of the Jenkins' Phantoscope. This is identical in all essentials with the method of television proposed by G. R. Carey, an American, and dated 1875 according to "La Television Electrique", by A. Dauvillier, published much later, in 1928, by *La Revue Generale de L'Electricite*, of Paris; while an illustrated description of Carey's method also appears in a copy I possess of *Design and Work* for June 25, 1880.

Historical Notes on Television Before 1900

By GEORGE SHIERS

The Carey Legend

The most prevalent version of the beginnings of television gives credit to an invention by George R. Carey of Boston in 1875. Carey did not claim this early date nor is it supported by contemporary reports. This story appeared, perhaps for the first time in English literature, nearly fifty years ago in a survey article[11] by Alan Archibald Campbell Swinton (1863–1930), well-known electrical engineer of London who was the first to suggest an all-electric television system. He stated:
